Abstract

Development of chemotherapy resistance is a major problem in ovarian cancer. One understudied mechanism of chemoresistance is the induction of quiescence, a reversible non-proliferative state. Unfortunately, little is known about regulators of quiescence. Here we identify the master transcription factor NFATC4 as a regulator of quiescence in ovarian cancer. NFATC4 is enriched in ovarian cancer stem-like cells (CSC) and correlates with decreased proliferation and poor prognosis. Treatment of cancer cells with cisplatin results in NFATC4 nuclear translocation and activation of NFATC4 pathway, while inhibition of the pathway increased chemotherapy response. Induction of NFATC4 activity results in a marked decrease in proliferation, G0 cell cycle arrest and chemotherapy resistance, both in vitro and in vivo. Finally, NFATC4 drives a quiescent phenotype in part via downregulation of MYC. Together these data identify that NFATC4 as a driver of quiescence and a potential new target to combat chemoresistance in ovarian cancer.
**Introduction**

Every year approximately 240,000 women are diagnosed with ovarian cancer worldwide, and 140,200 succumb to the disease (1). Among all cancers in developed countries, ovarian cancer has the third highest incidence:mortality ratio. Although initial response rates to cytoreductive surgery and primary chemotherapy can be as high as 70%, the vast majority of patients experience a cancer relapse, develop chemotherapy-resistant disease, and die of their cancer (2). Consequently, identifying and understanding mechanisms of chemotherapy resistance in ovarian cancer are essential for the development of new therapeutics to prevent relapse and improve overall survival.

Quiescence is defined as a reversible non-dividing state in which cells arrest in the G0 phase of the cell cycle. Adult stem cells are typically maintained in G0 until stimulated to enter the cell cycle and proliferate (3). As chemotherapy targets rapidly dividing cells, quiescent stem cells are innately resistant to these therapies (4). A striking example of this mechanism can be observed in the hair follicle, where the Nuclear Factor of Activated T-cells (NFAT) family member, NFAT1, drives Cyclin Dependent Kinase 4 (CDK4) downregulation in the stem cell pool to induce a quiescent state (5). During chemotherapy, the rapidly dividing follicular cells die resulting in hair loss; however, due to the NFAT1 induced quiescence, the stem cells survive allowing hair re-growth following cessation of therapy.

The role of quiescence in cancer is new area of research. Quiescent cancer stem-like cells (CSC) have been reported in leukemia, medulloblastoma and colon cancers (6–8). In some cases, the quiescence is niche dependent, driving CSCs resistance to chemotherapeutics and tumor recurrence (6–8). Consequently, successful targeting of quiescent CSCs may be essential for
Improving cancer cure rates (9). To date, little is known about regulators of quiescence in ovarian cancer.

We previously reported the identification of ovarian CSC populations defined by the expression of the stem cell makers aldehyde dehydrogenase (ALDH) and CD133 (10). Meeting the definition for CSCs proposed by Weinberg and colleagues (11), these cells had enhanced tumor initiation capacity, and the ability to both self-renew and asymmetrically divide (10,12). In addition, these cells exhibit increased resistance to chemotherapy (10). Here, we demonstrate that the NFAT family member NFATC4 (coding for the NFAT3 protein) is upregulated in ovarian CSCs and in response to chemotherapy undergoes cytoplasm to nuclear translocation and with subsequent activation of known NFATC4 target genes. Using two constitutively active NFATC4 constructs, we demonstrate that NFATC4 drives the induction of a quiescent state characterized by (i) decreased proliferation rates, (ii) smaller cell size, and (iii) arrest of cells in G0 (13). Furthermore, induction of NFATC4 conveyed growth arrest and chemoresistance both in vitro and in vivo. Suggesting, that NFATC4 driven quiescence is in part related to suppressed MYC activity, activation of NFATC4 results in suppression of MYC expression, and overexpression of MYC following induction of NFATC4 can partially rescue the quiescent phenotype.

Results

NFATC4 mRNA and activity are enriched in a population of slowly dividing CSC

NFAT family members have been linked with quiescence in hair follicle stem cells (5). We therefore evaluated the expression of NFAT family members in ovarian cancer stem-like
cells (CSC). We previously identified a subset of ovarian CSC marked by expression of ALDH and CD133 (10). Evaluation of NFAT family mRNAs in ALDH+/CD133+ ovarian CSC and ALDH/CD133- ovarian cancer bulk cells identified NFATC4 as upregulated (4-200 fold, p<0.05-0.001) in 3 independent late stage (III-IV) High-Grade Serous Carcinoma (HGSC) patient-derived ALDH+/CD133+ samples (Figure 1A). While not as prominent, NFATC4 expression is also enriched in slower growing CD133+CSC populations from OVSAHO and A2780 cell lines (cell lines chosen to have distinct CD133+ cell populations) (Figure 1B-C).

To agnostically determine if NFATC4 was enriched in slower proliferating cells, we used evaluated NFATC4 expression in slowly proliferating/vital dye retaining cells (14) in multiple ovarian cancer cell lines. Slow growing/dye retaining cells (Bright), demonstrated a significant enrichment for NFATC4 mRNA expression compared to the fast-growing (dim – dye dilute) cells in all four cell lines tested (HEY1 p<0.05, OVSAHO p<0.001, CaOV3 p<0.01, COV362 p<0.05) (Figure 2A). These slow dividing cells were also shown to be significantly enriched for ovarian CSC markers (Figure 1B).

Suggesting these findings may have clinical relevance, in silico analysis of the impact of NFATC4 expression on patient prognosis was performed using publicly available data (15,16). Analyses of microarray data from 1287 HGSC ovarian-cancer patients (16) suggested higher expression of NFATC4 is correlated with worse Overall Survival (OS), Progression Free Survival (PFS) and Post Progression Survival (PPS) (Figure 3A, p<0.01, p<0.0001, p<0.05). Similarly, analysis of 376 samples in the The Cancer Genome Atlas (TCGA) ovarian cancer data set, demonstrated that dysregulation of the NFATC4 pathway correlated with poor patient outcome (Supplementary Figure 1, p<0.05). Parallel analysis of NFATC4 target gene RCAN1, also showed a correlation between elevated expression and OS, PFS, and PPS (Figure 3B,
p<0.051, p<0.0001, p<0.05). The impact of RCAN1 on prognosis was less prominent but is likely complicated by RCAN1 expression in T cells.

NFATC4 activity induces a quiescent state

To directly interrogate the function of NFATC4 in ovarian cancer cells, we used two distinct previously generated NFATC4 expression constructs, a constitutively active (cNFATC4) (17) and an inducible (IcNFATC4) (18). NFAT proteins are primarily regulated through phosphorylation regulated cytoplasmic retention (dephosphorylation results in nuclear translocation and activation of transcription various binding partners (19,20)). One construct (cNFATC4) lacks the regulatory phosphorylation domain and is therefore constitutively nuclear/active (Figure 4A). Transfection of this construct into A2780 cells demonstrated clear expression of the NFATC4 mRNA relative to Control-YFP transfected cells (Figure 4B).

Confirming cNFATC4 is transcriptionally active, expression of cNFATC4 resulted in a strong induction of the known NFAT target genes RCAN1 (regulator of calcineurin-1) (21), and Follistatin (FST) (22) (Figure 4B). To confirm the was broadly applicable, we repeated this experiment and found similar results using multiple ovarian HGSC cell lines (CaOV3, COV362 and OVSAHO) (Figure 4B).

We also generated a doxycycline (Dox) inducible nuclear NFATC4 (IcNFATC4) with a puro selection cassette (Figure 4A). As deletion of the regulatory domain could lead to unexpected changes in function, we used a previously developed construct with point mutations that change the regulatory serines to alanines, leaving the remaining protein intact (18). Due to the lack of serine phosphorylation, this NFAT3 protein has an exposed nuclear localization.
sequence and is therefore constitutively nuclear. An inducible luciferase (ILuc) was used as a control. Disappointingly and inexplicably, despite clear presence of the construct, we were unable to show any inducible expression in multiple HGSC cell lines including OVSAHO, OVCAR3 and OVCAR4 (Supplemental Figure 2A). However, we were able to generate inducible expression of NFATC4 mRNAs in the HGSC cell line HEY1 (23), and the endometriod ovarian cancer SKOV3 line (Figure 4C). Suggesting activity of the IcNFATC4 construct, following doxycycline induction, the NFATC4 protein (NFAT3), is detected at high levels in the cell nucleus (Supplemental Figure 2B). Confirming transcriptional activity, the NFAT target genes RCAN1 and FST were induced following NFATC4 induction (Figure 2C).

Using these constructs, we tested the effects of NFATC4 activity on ovarian cancer cell growth. Compared to control-YFP lines, cNFATC4 overexpression was associated with a 2-fold (A2780) decrease in total cell number over four days (p<0.0001) (Figure 5A). Similarly, cNFATC4 overexpression in HGSC cell lines resulted in a 60% (COV362, P<0.001), 50% (OVSAHO, P<0.05) and 70% (CaOV3, P<0.01) decrease in total cell number compared to Control-YFP lines (Figure 5B).

For the IcNFATC4 constructs, doxycycline induction of two independent HEY1 IcNFATC4 cell clones and two independent SKOV3 cell clones showed 1.5-3 fold and 2-4 fold (p<0.01) decrease in cell number at 3 and 6 days after doxycycline treatment, respectively (Figure 5C). In contrast, doxycycline had no impact on ILuc cell growth for either cell line (Figure 5C). Interestingly, we noted that, despite multiple rounds of FACS enrichment, cNFATC4 expression, but not Control-YFP, was rapidly lost over time in cell culture, which could be due to selection for rapidly growing cells (Supplemental Figure 3).
Given the significant reduction in cell numbers and links between NFAT proteins and apoptosis (24), we evaluated the effects of NFATC4 on cellular viability. Trypan blue staining of A2780 and SKOV3 cells indicated that total viability did not change with the expression of cNFATC4 or IcNFATC4 (with or without dox) compared to their respective controls (Figure 5D). We also analyzed apoptosis rates in the HEY1 IcNFATC4 cells vs ILuc control with Annexin-V/PI FACS. We observed no significant increase in Annexin-V staining in IcNFATC4 cells vs. ILuc controls (Figure 5E). Thus, it does not appear that increased apoptosis rates account for the significant reduction in proliferation of NFATC4 overexpressing ovarian cancer cells.

Another explanation for a reduction in growth following overexpression of NFATC4 could be an increase in cellular senescence (25). Senescent cells demonstrate an increase in senescence-associated β-galactosidase (SABG). SABG staining demonstrated no increase in SABG expression in control or cNFATC4 cells compared with controls (Supplementary Figure 4A-B). Therefore, it appears that NFATC4 expression decreases cell division without inducing death, apoptosis, or senescence.

We next evaluated the impact of NFATC4 expression on cellular division. Suggesting a reduction in the percentage of dividing cells, immunofluorescent evaluation of BrdU incorporation demonstrated a reduction of BrdU incorporation in cNFATC4 cells (p<0.0001) (Figure 6A). We then evaluated cellular proliferation at a single cell level. We monitored cell divisions of cells expressing cNFATC4 or Control-YFP in single cell microfluidic culture chips (Table 1), described previously (12). Over four days, 39% of control cells and 20% of cNFATC4 cells underwent at least one cell division. 41% of dividing control cells underwent a second cell division while only 4% of the cNFATC4 cells underwent a second division; this resulted in a
final >3-fold decreased total cell number in the cNFATC4 cells vs. Control-YFP cells (Table 1). We also evaluated the impact of NFATC4 on growth rates of SKOV3 and HEY1 cell lines. Cells lines expressing the construct IcNFATC4 or ILuc were evaluated in the presence of doxycycline for 96 hours using real-time imaging. Doxycycline treated IcNFATC4 expressing cells had significantly slower proliferation rates than doxycycline treated ILuc controls (HEY1 p<0.0001, SKOV3 p<0.001), with near complete arrest at 96 hours (Figure 6B) (p<0.0001).

An explanation for restricted cell proliferation, in the absence of cell death or senescence, is the induction of quiescence. Quiescent cells typically exit the cell cycle and reside in G0. To directly evaluate the impact of NFATC4 activity on G0 cells, we transduced HEY1 cells expressing the IcNFATC4 and ILuc constructs with the mVenus-p27K- and mCherry-CDT1 vectors (13). This system can be used to define the G0/G1 transition; briefly, cells expressing high levels of each fusion protein (yellow) are in G0, cells with low or no mVenus-p27K- and high mCherry-CDT1 (red) are transitioning into G1 or in the G1/S phase, and cells with no/low expression of either construct are in S/G2/M. ILuc and IcNFATC4 cells were labeled with the two reporters and the cells expressing both reporter constructs were FACS isolated (Figure 6C). Purified cells were then treated with doxycycline, plated at ~10% confluency, allowed to adhere overnight before real-time imaging was performed over 90 hours. At the conclusion of the experiment, we scored the number of cells in each phase of the cell cycle found IcNFATC4 cells had a >4-fold increase in the number of cells in G0 (Figure 6C, P<0.01).

To determine if a subset of cells were cycling while a distinct subset was arresting in G0, we FACS isolated ILuc and IcNFATC4 cells in the G1/S phase of the cell cycle (mCherry-CDT1(+), mVenus-p27K(-)) of the cell cycle, re-plated and FACS analyzed after 72 hours. FACs analysis showed that while ILuc cells redistributed appropriately through the cell cycle with 39%
of cells in G1/S, nearly 90% of the IcNFATC4 cells were in the S/G2/M and G0 phases of the cell cycle with only 7% of cells in the G1/S phase of the cell cycle (Figure 6D).

In addition to G0 arrest, quiescent cells have a unique phenotype which includes a reduction in cell size (26). Light microscopic evaluation of doxycycline treated HEY1 and SKOV3 IcNFATC4 and ILuc controls, controlled for cell confluences (Supplemental Fig 5A) demonstrated IcNFATC4 cells became significantly smaller with doxycycline treatment (HEY1 p<0.01, SKOV3 p<0.001) (Figure 7A-B). FACS analyses of forward-scatter as another measure of size confirmed these results in A2780 cNFATC4 cells and doxycycline treated HEY1 IcNFATC4 cells (Supplementary Figure 5B-D).

NFATC4 overexpression promotes chemotherapy resistance in vitro

Multiple groups have reported that quiescent/slower-cycling cells are more chemotherapy resistant (27–29). We therefore tested the effects of constitutive NFATC4 expression on chemoresistance. We co-treated A2780 cells expressing the cNFATC4 or Control-YFP construct and SKOV3 expressing the IcNFATC4 or ILuc constructs with doxycycline and varying concentrations of cisplatin for 72h (for IC 50 values, see Supplementary Table 1). We then quantitated cell number and normalized to the untreated cells. cNFATC4 and IcNFATC4 cells demonstrated significantly increased survival (p<0.001 and p<0.01 respectively) in response to cisplatin chemotherapy when compared to Control-YFP and doxycycline treated ILuc (Figure 8A). SKOV3 expressing IcNFATC4 treated with and without doxycycline also showed a similar effect (Supplementary Figure 6, left graph P<0.01), while ILuc untreated vs doxycycline showed no difference (Supplementary Figure 6, right graph). To confirm these results, we co-
treated HEY1 and SKOV3 cells expressing the IcNFATC4 or ILuc control construct with
doxycycline and cisplatin (9.5 ug/ml) for 72h and measured cell confluency using the IncuCyte
real time imaging (Figure 8B). IcNFATC4 cells were significantly more resistant to
chemotherapy than ILuc cells for both HEY1 (p<0.0001) and SKOV3 (p<0.0001) cell lines.

Supporting these results, slower growing/NFATC4 enriched CD133+ A2780 and OVSAHO
CLSCs (Figure 1C), demonstrated resistance to cisplatin treatment (Figure 8C). A2780 CD133+
cells which had the highest levels of NFATC4 were most cisplatin resistant To functionally link
NFATC4 activity and chemotherapy resistance, we co-treated cell lines with the pan-NFAT
inhibitor VIVIT (30) and various concentrations of cisplatin for 72 hours. Cells co-treated with
VIVIT and cisplatin showed a significant decrease in cell viability when compared to cells
treated with cisplatin alone (A2780 p<0.05, SKOV3 p<0.05) (Figure 8D).

To determine if chemotherapy exposure could induce NFAT3 nuclear translocation, we
performed immunofluorescence on cisplatin treated ovarian cancer cell lines. Cisplatin
demonstrated clear nuclear translocation of native NFAT3 in all tested ovarian cancer cell lines
(Figure 9A). Confirming transcriptional activity of NFATC4 with cisplatin induced nuclear
translocation, cisplatin treatment resulted in increases in both RCAN1 mRNA (COV362
p<0.0001, SKOV3 P<0.01, HEY1 p<0.001, CaOV3 p<0.01) (Figure 9B), and FST mRNA
(COV362 p<0.01, HEY1 p<0.1, CaOV3 p<0.01) (Figure 9C). We also observed a significant
enrichment of NFATC4 mRNA expression (COV362 p<0.01, OVSAHO P<0.01, CaOV3
P<0.05), following prolonged treatment of a high dose of cisplatin for 72h (Figure 9C). Whether
this relates to an increase in NFAT gene expression in platinum treated cells, or selection for
cells expressing NFATC4 remains to be determined. Furthermore, NFAT3 protein levels were
demonstrated to be higher and more nuclear in chemoresistant ovarian cell lines compared to
their chemosensitive pairs (Supplementary Figure 7). Taken together, our in vitro data demonstrates NFATC4 promotes quiescence and chemoresistance in ovarian cancer cells and ovarian CSCs in vitro.

With NFATC4 clearly being activated by cisplatin, we wished to investigate if this response was specific to cisplatin or a general response to cellular stress. To test this, we Taxol treated ovarian cancer cell lines for 72h (for IC50 values see, Supplementary Table 1) and looked at expression of the same genes (Supplementary Figure 8). We demonstrated a mild increase in both RCAN1 and NFATC4 expression following Taxol treatment. This suggests, Taxol may contribute to activation of the NFATC4 pathway. However, platinum, which is known to increase intracellular calcium levels – a known activator NFAT nuclear localization, is likely the primary driver.

cNFATC4 expression suppresses tumor growth and drives chemotherapy resistance in vivo

We next examined the effect of NFATC4 expression on tumor xenograft growth. A2780 cNFATC4 tumors demonstrated significant growth delay relative to controls (p<0.0001), with essentially no growth for three weeks and with 2/10 cNFATC4 tumors failing to initiate (Figure 10A). qPCR analysis confirmed cNFATC4 tumors had higher expression of NFATC4 and RCAN1 compared to Control-YFP tumors (Figure 10B). After three weeks, cNFATC4 tumors resumed normal growth; however, suggesting a requirement for loss of cNFATC4 for resumption of growth, analysis of these tumors demonstrated complete loss of cNFATC4 transgene expression (Supplementary Figure 9).
We similarly evaluated the impact of IcNFATC4 expression on tumor growth. In the presence of continuous doxycycline treatment, tumors expressing IcNFATC4 were >13 fold smaller than their ILuc controls (p<0.0001) (Figure 10C). To confirm this was not related to unequal cell inoculation or altered tumor initiation, we repeated this experiment, but did not initiate doxycycline treatment until tumors were 100mm3. Control-Luc and IcNFATC4 tumors initiated and grew similarly. However, ~5 days after the initiation of treatment with doxycycline, IcNFATC4 tumors showed growth arrest (Figure 10D-E). Confirming reversibility of the phenotype, on withdrawal of doxycycline, after a slight delay, tumors resumed normal growth. Lastly, to confirm quiescence of the NFATC4 activated cells, we performed Ki67 immunofluorescence on IcNFATC4 tumors treated with or with doxycycline. Tumors treated with doxycycline had significantly less Ki67 positive staining compared to untreated tumors (p<0.0001) (Figure 10F), confirming NFATC4 induced quiescence.

We next tested the impact of IcNFATC4 induction on chemotherapy resistance. We allowed IcNFATC4 tumors to grow until they were ~150mm³. Tumor bearing mice were then randomized and half were then treated with doxycycline for 5 days to induce NFATC4 expression. Due to the low sensitivity of HEY1 to cisplatin at baseline, animals were treated with 2 daily doses of high-dose paclitaxel (16 mg/kg). While control tumors demonstrate a complete response to chemotherapy, tumors in which IcNFATC4 expression was transiently induced demonstrated growth arrest in response to doxycycline, and then ~8 days after doxycycline discontinuation, tumors resumed normal growth without any evidence of response to therapy (p<0.001) (Figure 10G).
NFATC4 downregulates MYC and MYC overexpression can partially inhibit early NFATC4 mediated quiescence

It has been reported by multiple studies that NFAT family members can regulate the proto-oncogene MYC (31–33). MYC is a master regulator of growth-promoting signal transduction pathways and a well-defined pro-proliferation gene (34). To determine if NFATC4, like other family NFAT family members, can regulate MYC expression and if this could be a mechanism for NFATC4 mediated quiescence, we examined the effect of cNFATC4 on MYC mRNA expression. HEY1 and SKOV3 cells demonstrated a significant reduction in MYC expression following NFATC4 induction, p<0.0001 and p<0.05 respectively (Figure 11A).

Furthermore, we conducted doxycycline recovery experiments, where we induced the construct by treating cells with doxycycline for 72h, then removed the doxycycline and recorded cell number (Supplementary Figure 10A) and mRNA expression of NFATC4 target genes (Supplementary Figure 11) as the cells resumed cell cycle. We were then able to re-induce the quiescent state via additional doxycycline treatment (Supplementary Figure 10B and 11).

These experiments demonstrated MYC, along with the NFATC4 target genes RCAN1 and FST, cycled with the induction and loss of quiescence, supporting their role in inducing this quiescent state.

To investigate if this downregulation in MYC following NFATC4 induction could affect cell proliferation, we transfected lcNFATC4 expressing SKOV3 and HEY1 cells with a MYC overexpression construct (35) or PCDNA3 vector control. MYC overexpression resulted in a significant increase in MYC mRNA expression (SKOV3 p<0.05, HEY1 p<0.01) (Figure 11B). To determine if early induction of MYC expression was able to prevent NFATC4 induced
quiescence, induced IcNFATC4 cells for 6 hours then transfected cells with PCDNA3 (control) or MYC. We continued doxycycline for 72 h before and then evaluated cell growth. Cells transfected with MYC 6 hours after NFATC4 induction demonstrated cell growth which was not statistically significantly different from control ILuc cells (Figure 11C).

To determine if MYC expression could overcome growth suppression in established NFATC4 driven quiescent cells we repeated the above experiment, in cells in which NFATC4 had been induced for 72 h to ensure the cells had already establish a quiescent phenotype before transfecting with PCDNA3 or MYC. Doxycycline treatment was continued for an additional 72 h before and cell proliferation evaluated. Interestingly, MYC expression in established quiescent cells was unable to reverse the quiescent phenotype (Figure 11C).

Discussion

The Nuclear Factor of Activated T-Cells (NFAT) family of transcription factors act as master regulators of numerous cellular processes. In normal cells, NFAT family members can impact both proliferation (36–40) and quiescence (5). NFAT proteins have been directly implicated in the regulation of stem cell proliferation (41). We report here a critical role for NFATC4 in the regulation of cellular quiescence in ovarian cancer. Expression of constitutively nuclear NFATC4 suppresses cellular proliferation, reduces cell size and arrested tumor growth. Furthermore, consistent with previous reports (42,43), we find that NFATC4 activity contributes to chemotherapy resistance, both in vitro and in vivo. Finally, NFATC4 induction represses MYC which contributes to a quiescent state.
NFAT family members and regulation of quiescence: We identified NFATC4 as a potential regulator of quiescence in ovarian cancer. Previously NFATC1 was identified as regulating quiescence in the hair follicle. More recently, a study of NFATC3 in the brain (44) observed significant changes in cell proliferation and vital dye retention with NFATC3 inhibition. These studies implicate the NFAT family of transcription factors as regulators of quiescence.

The complete mechanism through which NFAT regulates proliferation/quiescence is unclear. In the hair follicle, NFAT regulates the cyclin dependent kinase CDK4 to arrest cell cycle progression (5). We did not observe similar mechanisms here; however, we did observe NFATC4 expression correlated with a down regulation of MYC, while MYC overexpression was able to partially rescue the quiescent phenotype following early, but not late, induction of NFATC4. This observation suggests that although downregulation MYC could be an important part of the induction of a quiescent phenotype, there are secondary mechanisms downstream of NFATC4 which are critical in the maintenance of the quiescent state. Future work is required to elucidate the mechanism responsible for NFATC4 induced quiescence.

NFATC4 and chemotherapy resistance: NFATC4 has been poorly studied in cancer. In normal physiologic states, NFATC4 appears to function partly as a general stress response protein, as it serves a protective role in cardiomyocytes in response to radiation (45), is activated by mechanical stress in the heart (46) and bladder (47), and serves as a protective factor during hypoxia (48). NFATC4 may serve as a similar stress regulator in cancer cells to promote survival. We have shown that NFATC4 translocates to the nucleus and initiates transcription in response to cisplatin chemotherapy and drives chemotherapy resistance. Similarly, NFATC4 expression was linked with therapeutic response in gastric cancer (49). Taxol’s partial induction
the \textit{NFATC4} pathway of may be a result of its limited ability to increase intracellular calcium (50), while increasing intracellular calcium is a key mechanism by which cisplatin functions (51).

Consistent with a role for \textit{NFATC4} in cancer stem-like cells, \textit{NFATC4} plays a role in pancreatic cell plasticity and tumor initiation (52). Consistent with the data above, survival data demonstrating dysregulation or high expression of \textit{NFATC4} leads to worse prognosis of ovarian cancer patients, suggest \textit{NFATC4} may be an important therapeutic target in ovarian cancer to overcome the chemotherapy resistance associated with slow-cycling cells. This hypothesis is supported by studies on cyclosporine, a commonly used immunosuppressant which inhibits the NFAT family. Cyclosporine has shown activity as a chemo-sensitizer in a phase II clinical trial, demonstrating that cyclosporine could improve response to therapy in patients with chemotherapy-refractory disease (53,54). However, this has not been reproducible (55) and has not been tested in patients with chemotherapy naïve disease, who may benefit the most from the elimination of slow cycling cells. Furthermore, as cyclosporine impacts all NFAT family members, and is not selective for cancer cells, suppression of immunity may limit efficacy.

\textit{NFATC4} is the only core NFAT family member that is not expressed in the immune system (56), thus the development of specific \textit{NFATC4} inhibitors could allow chemosensitization of the \textit{NFATC4}-expressing CSC without concomitant immunosuppression.

In summary, we have found that the master transcriptional regulator \textit{NFATC4} induces a quiescent state in ovarian cancer and translocates to the nucleus in response to chemotherapy. Constitutively nuclear \textit{NFATC4} is associated with a reduction in cellular size and proliferation and the induction of chemotherapy resistance. \textit{NFATC4} promotes the quiescent phenotype by early downregulation of \textit{MYC}; however other mechanisms are responsible for maintaining an
established quiescent phenotype. Taken together, this data suggest NFATC4 is an important therapeutic target in ovarian cancer that warrants significant further investigation.

Materials and Methods

Cell Culture

The A2780 cell line was obtained from Dr. Susan Murphy at Duke University. SKOV3, CaOV3 and HEY1 lines were purchased from ATCC (2018). OVSAHO cells were gifted from Dr. Deborah Marsh from the University of Sydney (Sydney, NSW, Australia). COV362 were purchased from Sigma- Aldrich (2018). All cells were cultured in RPMI-1640 media with 10% FBS, 1% Penicillin/Strepto MYC in at 37°C and 5% CO2.

Constructs

Both constructs used in this study were designed to result in constitutively nuclear NFATC4. A constitutively nuclear NFATC4-YFP fusion (cNFATC4) with the phospho-regulatory domain deleted or a YFP-only control (Control-YFP) were cloned into a pGIPZ lentiviral vector and transduced into the A2780, CaOV3, OVSAHO and COV362 ovarian cancer cell lines. A second, phospho-specific mutant constitutively active NFATC4 (18) was also cloned into the doxycycline-inducible Tet-One expression system (Clontech) to create an inducible and constitutive NFATC4 (IcNFATC4) in the HEY1 ovarian cancer line. This was paired with an inducible luciferase control (ILuc) to control for overexpression. Details regarding the structure and validation of all constructs are presented in the results section (Figure 4). Because the only known function of NFAT proteins are transcription, the phospho-mutants used are constitutively
nuclear and therefore constitutively active. A pcDNA3-MYC construct was purchased from Addgene (Cat# 16011).

**Patient samples**

Fresh High-grade Serious Ovarian Carcinomas (HGSOC) were acquired from the University of Michigan’s Comprehensive Cancer Center. Fresh tumor samples were dissociated using a Tumor Dissociation Kit (Miltenyi Biotec) and cultured using standard conditions. HGSOC diagnosis was confirmed using immunohistochemistry. All the patient tumor samples used were derived from primary debulking of patients with stage IIIC high grade serous carcinoma.

**Carboxyfluorescein succinimidyl ester (CFSE) Assay**

HEY1, COV362, OVSAHO and CaOV3 cell lines were stained with 2.5 uM of CellTrace™ CFSE Cell Proliferation Kit (Thermo Fisher) for 20 mins at 37°C, washed and then grown for 5-7 days. The top 4% bright cells, 10% medium cells and bottom 4% dim cells were FACS isolated. RNA was extracted, and qPCR performed to validate NFATC4 expression (as below).

**Quantitative PCR**

RNA was extracted using RNeasy Mini Kit (Qiagen) and cDNA was made using SuperScript™ III Reverse Transcriptase kit (Theremofisher). qPCR was performed using SYBR™ Green PCR Master Mix (Applied Biosystems) using standard cycling conditions. The primers used for this study are available in supplemental material (Supplementary Table 2).
Cell counting

Cell counts were performed using the Moxi Z automated counting system (ORLFO Technologies) and the Cassettes Type S. For trypan blue staining, the Countess automated cell counter (Invitrogen) was used with Countess Cell Counting Chamber Slides.

BrdU labeling

A2780 cells were treated with 10 µM BrdU labeling solution and incubated for 4 hours at 37ºC in a CO2 incubator. Cells were washed with PBS, fixed with 4% paraformaldehyde and permeabilized with 0.1% Triton X. Standard ICC was followed. Cells were then incubated in 2.5 M HCL for 30 mins at room temperature, then washed with PBS. Standard immunocytochemistry protocol was then followed.

Micro Fluidics

A2780 Control-YFP or cNFATC4 cells were loaded into single cell capture microfluidic chips from collaborator Dr. Yoon (University of Michigan). Cells mitoses were tracked using a microscope over a three-day period and results were recorded. Cell viability was confirmed using LIVE/DEAD cell staining at the termination of the experiment.

Size Analysis

HEY1 and SKOV3 cells expressing the ILuc and IcNFATC4 constructs were pre-treated with doxycycline, then plated into a 96 well plate at 300 and 1000 cell/well respectively and placed into the IncuCyte. Cells were treated with or without doxycycline and grown for 36 h. Images were taken at 36 hours making sure the confluency was comparable between the doxycycline treated
and untreated control cells (Supplementary Figure 5A). Images were imported into ImageJ and cell size was calculated by drawing around cells and quantifying their area.

*Fluorescence ubiquitination cell cycle indicator (FUCCI)*

HEY1 cells expressing the IcNFATC4 or ILuc constructs were transduced with the p27-mVenus and CDT1-mCherry FUCCI cell cycle reporter constructs (13). Cells expressing both constructs were isolated using FACS and plated in the IncuCyte and grown for 90 hours. Fluorescence was measured, and percentages of green, red, yellow, and unstained cells were quantitated. G1-S phase cells expressing the constructs were FACS isolated and grown for 3 additional days to determine if they retained the cell cycle phases as a result of the NFATC4 overexpression.

*Annexin V staining*

For apoptosis detection via annexin staining, HEY1 ILuc and IcNFATC4 cells were grown in 6 well dishes with or without doxycycline for 72 hrs. Cells were stained with the Annexin-V FITC apoptosis kit (BD Biosciences) according to the manufacturer’s instructions and at least 10,000 events were analyzed on the Mo Flo Astrios flow cytometer (BD Biosciences). The percentage of Annexin V+, PI+, Annexin V+/PI+, and Annexin V-/PI- cells was quantified.

*Senescence-associated beta galactosidase (SABG) staining*

Cells were plated on tissue culture coverslips, allowed to grow for 96 hours, fixed, and then SABG staining was done as previously described (57).

*IncuCyte growth curves*

HEY1 and SKOV3 cells expressing the ILuc or IcNFATC4 constructs were seeded at 300 and 1000 cells per well respectively, in a 96 well plate. For growth curves, cells were treated with or
without 100 ng/mL doxycycline for 96 h. For cisplatin curves, cells were treated with 9.5 ug/mL cisplatin for 72h with or without co-treatment with 100 ng/mL dox. IncuCyte images were taken every 4 h and cell confluence was recorded.

**Immunofluorescence**

Cells lines, or frozen tissue sections were fixed with 4% paraformaldehyde and permeabilized with 0.1% Triton X. Cells were blocked with 10% horse serum or 2% BSA and incubated with 1:100 mouse anti-NFATC4 antibody (Sanat Cruz, sc-271597) or 1:200 rabbit anti-MKI67 antibody (Sigma, HPA000451) in 0.5% BSA overnight or 5% horse serum for 2 hours. Slides were washed 3 x 5 mins with PBS, cells were incubated with an Alexa Fluor 488 anti-mouse or Cy5 anti-rabbit secondary antibody (both 1:500, Thermo Fisher Scientific), mounted with DAPI mounting medium (Vector Labs), and then imaged on an Olympus BX41 microscope.

**In vivo xenografts**

*NOD/SCID/IL2RKO* or nude mice (colonies maintained from the University of Michigan and the University of Pittsburgh) were injected with 500,000 Control-YFP or cNFATC4 cells or 300,000 ILuc or IcNFATC4 cells for tumor xenograft experiments. Animals were maintained at 12 hour light/dark cycles under SPF conditions with free access to food and water. For induction, 2 mg/mL doxycycline was administered in the water along with 5% sucrose to mask its bitter taste. Tumors were monitored once a week initially and twice a week after tumors reached 1000 mm³, and animals were sacrificed at protocol endpoints. All experiments were conducted in accordance with the animal care and use committee from the University of Michigan.
Statistical analysis

Statistically analysis was conducted using GraphPad Prism (8.0.2) and http://vassarstats.net/. All data was analyzed using two tailed student’s t-tests or one-way ANNOVARs. Data represent mean ± SEM. A P value of less than 0.05 was considered to be statistically significant.

Study approval

Informed consent was obtained from all patients before tissue procurement. All studies were performed with the approval of the Institutional Review Board of the University of Michigan. All mouse experiments were conducted with approval of the University Committee on Use and Care of Animals at the University of Michigan and the University of Pittsburgh.
Author Contributions

A.C and M.I conducted the majority of the experiments. R.B and S.B conceived the project and planned the experiments. S.P-G, P.H, E.Y and D.H. helped with the experiments. G.D., K.A., E.Y reviewed the manuscript. A.C, M.I and R.B. wrote the manuscript.
