Supplementary Figure 1. Adoptive co-transfer of CD19^+^ cells purified from 6-week-old NOD donors does not increase peripheral M1 macrophage populations nor increase circulating levels of anti-inflammatory cytokines.

Serum was collected from NOD.scid recipients receiving either splenocytes from a diabetic NOD donor, diabetic splenocytes and (A) Representative staining for macrophages with cells initially gated on CD11c^-^CD16/32^+, and then sub-gated on the Mac-1^-^F4/80^+^ group (upper right quadrant) of M1 macrophages. (B) CD11c^-^CD16/32^+^Mac-1^-^F4/80^+^ M1 macrophages were analyzed in 26 NOD.scid recipients, and total M1 macrophages were calculated using the percentage subgroup populations with non-significant p-values calculated using a non-parametric t-test with Welch’s correlation. CD19^+^ cells from 6-wk-old NOD donors, or splenocytes from a diabetic NOD donor with CD19^+^ cells from >15-wk-old NOD donors. The presence of (C) IL-4. (D) IL-10 was analyzed by ELISA.
